Lattice path combinatorics has developed greatly as a branch of probability studies recently, and the need for new books on the subject is obvious. It treats several recent results and it offers a powerful new tool for studying many problems in mathematical statistics. eISBN: 978-1-4875-8258-6. Just as in the seventeenth century when the beginnings of combinatorial analysis coincided with those of probability theory, many pleasing advances in both combinatorial theory and probability theory have been made in the last twenty-five years. As one example, we prove (and slightly extend) a celebrated theorem of Chung and Feller (1949). Lattice path combinatorics have a variety of applications: ballot numbers and its variants [7], moments of orthogonal polynomials [6], Smirnov test statistics, knock out tournaments and convolution identities (see, e.g. [1]), to name a few. The statistical applications arise from comparing collections of independent and identically distributed random variables. In this paper, we enumerate so-called k -exceedant paths and produce a probability distribution to compare the failure rates between two parallel systems whose components consist of independent and identically distributed random variables. [2] K.Chung and K. Feller, Lattice path combinatorics with statistical applications, Mathematical Expositions. no. 23, Toronto Press, 1979. Lattice path combinatorics has developed greatly as a branch of probability studies recently, and the need for new books on the subject is obvious. The present monograph, by one who has made significant contributions to combinatorics and its applications to probability and statistics, will be useful to research workers, teachers, professional statisticians, and advanced students alike. It treats several recent results and it offers a powerful new tool for studying many problems in mathematical statistics. The emphasis in the five chapters is on 'dominance.'
