Such deliberate therapeutic applications may be considered the proper role of medical pharmacology, which is often defined as the science of substances used to prevent, diagnose, and treat disease. Toxicology is that branch of pharmacology which deals with the undesirable effects of chemicals on living systems, from individual cells to complex ecosystems. As new concepts and new techniques were introduced, information accumulated about drug action and the biologic substrate of that action, the receptor. During the last half-century, many fundamentally new drug groups and new members of old groups were introduced. Conversely, lack of understanding of basic scientific principles in biology and statistics @inproceedings{Munson1995PrinciplesOP, title={Principles of pharmacology : basic concepts and clinical applications}, author={Paul Lewis Munson and Robert A. Non-clinical pharmacological studies allow scientists to compare a medicine's beneficial effects with its negative (toxic) effects. This comparison is important so that a thorough benefit-risk analysis can be made before proceeding to test the medicine in clinical (human) studies. If the medicine does proceed to the clinical phase, data gathered during non-clinical pharmacology and toxicology studies help to determine the dosage of medicine given to volunteers in the first clinical studies (first-in-human). The key principles of Pharmacokinetics "the study of the effect the body has on a medicine" are represented in the acronym ADME. Data gathered during pharmacokinetic studies provide information about what happens to a medicine in the body over time.

Clinical pharmacology is the science of drugs in humans and their optimal clinical use in patients. It is underpinned by the basic science of pharmacology, with an added focus on the application of pharmacological principles and quantitative methods in the real human patient's population. It has a broad scope, from the discovery of new target molecules to the effects of drug usage in whole populations.
