Stress corrosion cracking is a failure mode which has occurred with increasing frequency in both the military and the civilian sectors as our technological way of life has increased in complexity. III. Theory IV. References Chapter 2. Test methods and Interpretation of Test Data. I. Smooth specimen tests under static loads II. Pre-cracked (fracture mechanics) specimens under static loads. Stress corrosion cracking (SCC) is characterized by cracks propagating either transgranularly or intergranularly (along grain boundaries). There are several types of stress corrosion cracking (SCC), for example, chloride-induced SCC and H₂S-induced SCC. Stress corrosion cracking (SCC) results from the combined action of three factors: Tensile stresses in the material. Chloride-induced SCC is tested experimentally in the laboratory using a chloride-containing environment. Testing can be carried out, for example, in boiling 40% CaCl₂ or chloride-containing water. Grades with high resistance to chloride-induced stress corrosion cracking (SCC). Duplex stainless steels, austenitic stainless steels with a high nickel content (> 25%).
